March 11, 1974

Professor I. M. Singer
Department of Mathematics
Massachusetts Institute of Technology
Cambridge, Massachusetts 02139

Dear Singer:

I will tell you what I can about the alternating sum in which you are interested, sometimes in my own idiom and sometimes in the classical. Because of this you may well wish to pass over some parts of the letter very quickly. I shall first give an expression for the alternating sum in terms of class numbers and then a second expression in terms of the values of $L$-functions.

The formulae I shall give, special cases of which are already to be found in Hecke, are consequences of some joint work with Jean-Pierre Labesse which, because of my dilatoriness, is not yet written up. It is therefore a little reckless of me to state them in an apodictic form. I recommend in fact that they be treated with some circumspection. I would be glad to give you an idea of the proof orally now and then, if you wanted them, could send you the details later. They are however rather complicated and involve considerable computation. I suspect that it would be easier for you just to sit down and apply the trace formula to your particular case and let the result fall out – it is not really very difficult.

Take $F$ to be a totally real field and let $G$ be the group $SL(2)$ over $F$. If $S_{\infty}$ is the set of infinite places of $F$ and $K_{\infty}$ is a maximal compact subgroup of

$$\Pi_{v \in S_{\infty}} G(F_v) = SL(2, \mathbb{R})^{[F: \mathbb{Q}]}$$

then to specify a complex structure on

$$\Pi_{v \in S_{\infty}} G(F_v)/K_{\infty}$$
we have to give for each \( v \) an imbedding of the circle group

\[ S^1 = \{ z \in \mathbb{C}^X \mid |z| = 1 \}. \]

in \( G(F_v) \). The complex structure is defined by the condition that the eigenvalues of \( \Pi_v \psi_v(e^{ix_v}) \) on the complex tangent space to the point fixed by \( \Pi_v \) under \( \Pi_v \psi_v \) are the numbers \( e^{2i x_v} \).

On the other hand given \( \psi_v \) and a character \( \theta_v \) of \( S^1 \) one can define two infinite-dimensional unitary representations \( \pi^1(\theta_v) \) and \( \pi^{-1}(\theta_v) \) of \( G(F_v) \). If

\[ \theta(e^{ix_v}) = e^{in_v x_v} \]

and \( n_v \neq 0 \) then \( \pi^1(\theta_v) \) and \( \pi^{-1}(\theta_v) \) are the holomorphic and anti-holomorphic discrete series of parameter \( |n_v| \). If \( T_\infty \subseteq S_\infty \) is given, the dimension of the space of cusp forms on \( G(O_F) \backslash \Pi G(F_v)/K_\infty \) of weight \( |n_v| + 1 \) at \( v \) which are holomorphic for \( v \in T_\infty \) and anti-holomorphic for \( v \in S - T_\infty \) is the multiplicity \( m(\{\epsilon_v\}, \{\theta_v\}) \) with which \( \otimes_v \pi^{\epsilon_v}(\theta_v) \), \( \epsilon_v = 1, v \in T_\infty, \epsilon_v = -1, v \in S_\infty - T_\infty \) occurs in the space of cusp forms in \( L^2(G(O_F) \backslash \Pi G(F_v)) \).

I believe you want a formula for

\[ \Sigma_{\{\epsilon_v\}}(\Pi_v \epsilon_v)m(\{\epsilon_v\}, \{\theta_v\}). \]

\( O_F \) is of course the ring of integers in \( F \).

Let \( \hat{A} \) be the group of adèles of \( F \), \( \hat{A}_f \) the adèles which are 1 at every infinite place, and \( \hat{O}_F \) the integral adèles in \( \hat{A}_f \). Then

\[ G(O_F) \backslash \Pi_v G(F_v) = G(F) \backslash G(\hat{A})/G(\hat{O}_F). \]

Every irreducible representation \( \pi \) of \( G(\hat{A}) \) which occurs in the space of cusp forms in \( L^2(G(F) \backslash G(\hat{A})) \) is of the form

\[ (\otimes_{v \in S_\infty} \pi_v) \otimes \pi_f \]
where $\pi_v$ is a representation of $G(F_v)$ and $\pi_f$ a representation of $G(\mathbb{A}_f)$. (5) It is a fact that $\pi_f$ contains the trivial representation of $G(\hat{O}_F)$ either once or not at all. The representation of $G(\mathbb{A})$ on the space of cusp forms is a discrete direct sum

$$\oplus m(\pi)\pi, \quad m(\pi) > 0 \text{ in } \mathbb{Z}.$$ (2)

For a given collection of $\theta_v$, $m(\{\epsilon_v\}, \{\theta_v\})$ is the number of $\pi$ counted with multiplicity for which $\pi_v$ is equivalent to $\pi^{\epsilon_v}(\theta_v)$ for each $v \in S_\infty$ and $\pi_f$ contains the trivial representation of $G(\hat{O}_F)$.

The expression (2) decomposes into three parts.

(3) The sum over all $\pi$ such that, for some $v$, $\pi_v$ is equivalent to no $\pi^{\epsilon_v}(\theta_v)$,

$$\oplus m(\pi)\pi.$$ (3)

(4) A sum over all $\pi$ such that, for each $v$, $\pi_v$ is equivalent to some $\pi^{\epsilon_v}(\theta_v)$,

$$\oplus m'(\pi)\pi.$$ (4)

Here $m'(\pi) \in \mathbb{R}$ and

$$m'((\bigotimes_v \pi^{\epsilon_v}(\theta_v)) \otimes \pi_f)$$

is independent of the $\epsilon_v$.

(5) A sum over the same $\pi$ as in (4)

$$\oplus m''(\pi)\pi.$$ (5)

Here $m''(\pi) \in \mathbb{R}$ and

$$\sum_{\{\epsilon_v\}} m''((\bigotimes_v \pi^{\epsilon_v}(\theta_v)) \otimes \pi_f) = 0.$$ (5)

You will agree I hope that the alternating sum (1) is affected by (5) alone. What I do now is give an explicit formula for (5) in terms of totally imaginary quadratic extensions of $F$. Then from this explicit form I single out the part corresponding to those $\pi$ for which $\pi_f$ contains the
trivial representation of $G(\hat{O}_F)$. The next part of the letter you will very likely prefer not to read. Nonetheless it's safer not to omit it.

The sum (5) will break up further into a sum over the totally imaginary quadratic extensions $E$ of $F$. I consider the term corresponding to a single $E$. Fix a basis $\lambda_1, \lambda_2$ of $E$ over $F$. For each $v \in S_\infty$ this gives a basis of $E_v = E \otimes F_v$ over $F_v$. If $\alpha \in E_v$ let

$$
\begin{pmatrix}
\alpha \lambda_1 \\
\alpha \lambda_2
\end{pmatrix} =
\begin{pmatrix}
a \lambda_1 + c \lambda_2 \\
b \lambda_1 + d \lambda_2
\end{pmatrix}.
$$

We identify $E_v$ with $\mathbb{C}$ in such a way that if $a \leftrightarrow e^{ix}$ then

$$
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}
$$

is conjugate to $\psi_v(e^{ix})$ under $G(F_v) \sim SL(2, \mathbb{R})$. Choose $t_0 \in E$ so that $\text{Im} \ t_0 > 0$ in each $E_v, v \in S_\infty$.

$\lambda_1, \lambda_2$ and $t_0$ are now fixed. Let $v$ be a finite place of $F$, let $E_v = E \otimes F_v, H_v = \{\alpha \in E_v | \text{rmN}_{E_v/F_v} \alpha = 1\}$, and let $\theta_v$ be a character of $H_v$.

(i) If $v$ splits in $E$ so that $E_v \cong F_v \oplus F_v$ it is possible to define a representation $\pi(\theta_v)$ of $G(F_v) = SL(2, F_v)$ with the following properties:

(a) If $\theta_v^2 = 1, \theta_v \neq 1$ then $\pi(\theta_v)$ is irreducible. Otherwise it is the direct sum of two irreducible representations.

(b) $\pi(\theta_v)$ contains the trivial representation of $G(O_F)$ if and only if $\theta_v$ is unramified, that is, trivial on $\{(\alpha, \alpha^{-1}) | \alpha \in O_{F_v}^X \} \subset F_v^+ \oplus F_v \cong E_v$ and then it contains it exactly once.

(ii) If $v$ does not split then it is possible to define two representations $\pi^1(\theta_v)$ and $\pi^{-1}(\theta_v)$ with the following properties:

(a) If $\theta_v^2 = 1, \theta_v \neq 1$ then $\pi^1(\theta_v), \pi^{-1}(\theta_v)$ are irreducible. Otherwise they are the direct sum of two one-dimensional representations.

(b) $\pi^1(\theta_v) + \pi^{-1}(\theta_v)$ contains the trivial representation of $G(O_{F_v})$ if and only if $E$ is unramified at $v$ and $\theta_v$ is trivial. Then it contains it exactly once. If $\varpi$ is a generator of the
prime ideal in $O_{F_v}$ and if $\ell_v$ is defined by $|t_0 - 7_0|_v = |\pi_v|^\ell_v$, if $\mu_1, \mu_2$ form a basis of $O_{E_v}$ over $O_{F_v}$, if

$$\begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \lambda_1 \\ \lambda_2 \end{pmatrix},$$

if

$$|ad - bc|_v = |\pi_v|_v,$$

then the trivial representation of $G(O_{F_v})$ is contained in

$$\pi^{(-1)^{-\ell_v}}(1).$$

Thus the distinction between $\pi^1(\theta_v)$ and $\pi^{-1}(\theta_v)$ depends on the choice of $\lambda_1, \lambda_2$ and $t_0$.

Let $H(\mathbb{A})$ be the idèles of $E$ which have norm 1 over $F$ and let $H(\mathbb{Q})$ be the elements of $E$ which have norm 1 in $F$. We have

**THEOREM:** The sum (5) is a sum over the total imaginary quadratic extensions of

$$\sum_{\theta \neq 1} \otimes_v \left[ \frac{\pi^1(\theta_v)}{\pi^{-1}(\theta_v)} \right] + \sum_{\{\theta, \theta^{-1}\}} \otimes_v \left[ \frac{\pi^1(\theta_v)}{\pi^{-1}(\theta_v)} \right].$$

**Explanation.** Here the sum is over characters of the compact group $H(F) \setminus H(\mathbb{A})$. In the first part $\theta$ and $\theta^{-1}$ are grouped together. Moreover the tensor product is taken over all places, finite and infinite. At a finite split place we put $\pi(\theta_v)$ and at an infinite place or a finite place which does not split we put $\pi^1(\theta_v) - \pi^{-1}(\theta_v)$. Here $\theta_v$ is the restriction of $\theta$ to $H_v \subseteq H(\mathbb{A})$. Notice that if $v \in S_{\infty}$ then $H_v \simeq \psi_v(S^1) \simeq S^1$ so that $\pi^1(\theta_v)$ and $\pi^{-1}(\theta_v)$ are defined. The literal meaning of the tensor products is as follows. One interchanges the tensor product with the sums, expands the result into an infinite sum of tensor products, discards those for which an infinite number of minus signs occur, and keeps the rest, each provided with a well-determined sign. Since any given representation will only occur a finite number of times in the sum one can then collect terms.
APPLICATION: When evaluating the sum (1) we are only interested in those representations such that
\[ \pi_f = \bigotimes_{\nu \text{ finite}} \pi_{\nu} \]
contains the trivial representation of \( G(\hat{O}_F) \), that is each \( \pi_{\nu} \) contains the trivial representation of \( G(O_{F_{\nu}}) \). By (ii, b) a given \( E \) yields a non-zero contribution only if it is unramified everywhere. In particular if \( F \) has a unit of norm -1, there is no such \( E \) and we have the trivial fact.

If \( F \) contains a unit of norm -1 the sum (1) is 0.

Let’s calculate the contribution of a given unramified field \( E \) to

\[
\Sigma_{\{\epsilon_{\nu}\}} (\Pi_{\nu} \epsilon_{\nu}) m(\{\epsilon_{\nu}\}, \{\theta^o_{\nu}\})
\]

where the \( n^o_{\nu} \) are given and
\[
\theta^o_{\nu}(e^{ix_{\nu}}) = e^{in^o_{\nu} x_{\nu}}, \quad v \in S_\infty.
\]

To avoid complications which are irrelevant for your purposes suppose \( n^o_{\nu} \neq 0 \) for at least one \( v \). Let \( \{n_{\nu}\} \) at first run over all collections such that \( n_{\nu} = \pm n^o_{\nu} \). However if \( w \) is a generator of the roots of unity in \( E \) we then restrict to those \( \{n_{\nu}\} \) such that

\[
\pi_{\nu} w_{\nu}^{n_{\nu}} = 1.
\]

Here \( w_{\nu} \) is the image of \( w \) under \( E \to E_{\nu} \to \mathbb{C} \). (Recall that we had earlier identified \( E_{\nu} \) with \( \mathbb{C} \) in a certain way.) Let the number of such collections \( \{n_{\nu}\} \) be \( \delta_E(\{\theta^o_{\nu}\}) \). Let the quotient of the ideal class group of \( E \) by the image of the ideal class group of \( F \) have order \( \epsilon(E/F) \). If \( \{n_{\nu}\} \) satisfies (6) the number of characters \( \theta \) of \( H(F) \backslash H(\mathbb{A}) \) such that \( \theta \) restricted to \( H_{\nu} \) is \( \theta_{\nu} \), with \( \theta_{\nu}(e^{ix_{\nu}}) = e^{in_{\nu} x_{\nu}}, \) for \( v \in S_\infty \) is \( \epsilon(E/F) \).

Finally if \( k_{\nu} \) and \( \ell_{\nu} \) are defined as before in terms of \( \lambda_1, \lambda_2 \), and \( t_0 \) then \( k_{\nu} = \ell_{\nu} = 0 \) for almost all \( v \) which do not split in \( E \) and we may set \( \mu(E/F) \) equal to the product over all finite places \( v \) which do not split in \( E \) of \((-1)^{k_{\nu}+\ell_{\nu}}\).
The sum (1) is equal to

$$2^{[F:Q]} - 2 \sum_{E} \mu(E/F) \epsilon(E/F) \delta_E(\{\theta_v^0\})$$

The sum, which is finite, is taken over all unramified quadratic extensions $E$ of $F$.

**Example.** Take $F$ to be the real quadratic extension $\mathbb{Q}(\sqrt{p})$, $p$ a prime. One can sometimes use information from the *Zahlbericht* to simplify the expression above. If $p \equiv 1 \pmod{4}$ and the fundamental unit has norm +1 there is one totally imaginary quadratic extension. If $p \equiv 3 \pmod{4}$ then the fundamental unit necessarily has norm +1 and there is again exactly one totally imaginary quadratic extension. It is in fact

$$\mathbb{Q}(\sqrt{-p}, \sqrt{p}) = \mathbb{Q}(\sqrt{-1}, \sqrt{p}).$$

In either case if an ideal class $\mathfrak{q}$ of $F$ becomes trivial in $E$ then $\mathfrak{q} \mathfrak{Q} = \mathfrak{q}^2$ is principal. Since $F$ has no ambiguous classes $\mathfrak{q}$ itself must be trivial so

$$\epsilon(E/F) = \frac{\epsilon(E)}{\epsilon(F)}$$

if $\epsilon(E)$ and $\epsilon(F)$ are the class numbers of $E$ and $F$ respectively.

Suppose $p \equiv 3 \pmod{4}$. Let (2) = $\mathfrak{A}^2$ where $\mathfrak{A}$ is an ideal of $F$. Since $F$ has no non-trivial ambiguous classes $\mathfrak{A}$ is principal. From §10 of Hilbert’s *Über den Dirichletschen biquadratischen Zahlkörper* we conclude that

$$\frac{\epsilon(E)}{\epsilon(F)} = \epsilon(\mathbb{Q}(\sqrt{-p})).$$

If $p \neq 3$ the generator of the roots of unity in $E$ is $\sqrt{-1}$. Thus if $n_v^0 = 1$ for both infinite $v$, the case in which you are principally interested,

$$\delta_E(\{\theta_v^0\}) = 2.$$
The choice of \( t_0 \) depends on the choice of the \( \psi_v \), that is on the choice of complex structure. For simplicity suppose that the \( \psi_v \) have been so chosen that \( t_0 \) may be taken as \( \sqrt{-1} \). Then all \( \ell_v \) are either 0 or 2, in fact \( \ell_v \) is 0, if \( v \) does not divide 2 and 2 if \( v \) is the unique place dividing 2. We may take \( \lambda_1, \lambda_2 \) to be 1, \( \sqrt{-1} \). Hilbert, in the paper to which I just referred, gives an integral basis for \( E \) from which it follows that \( k_v \) is 0 if \( v \) does not divide 2 but is 2 if \( v \) divides 2. Thus the sum (1) is equal to

\[
2\epsilon(\mathbb{Q}(\sqrt{-p}))
\]

**Evaluation in terms of \( L \)-functions.** You are primarily interested in evaluating (1) in terms of the values of \( L \)-functions. For this one should, in order to disencumber oneself of the fixed points, work not with \( G(\mathcal{O}_F) \) but with a congruence subgroup \( \Gamma(N) \). for \( N \) sufficiently large. The same two interpretations of (1) are still valid. Of course

\[
G(\mathcal{O}_F) \backslash \prod_{v \in S_\infty} G(F_v)
\]

is to be replaced by

\[
\Gamma(N) \backslash \prod_{v \in S_\infty} G(F_v) = G(F) \backslash G(\mathbb{A})/K(N)
\]

where

\[
K(N) = \{ g \in G(\hat{\mathcal{O}}_F) | g \equiv 1 (mod \ N) \}.
\]

We assume that no element of \( \Gamma(N) \) has a fixed point in

\[
\prod_{v \in S_\infty} G(F_v) \backslash K_{\infty}.
\]

In particular \( 2 \not\equiv (mod \ N) \).

We again want an expression for

\[
(1) \quad \Sigma_{\{\epsilon_v\}} (\Pi_v \epsilon_v) m(\{\epsilon_v\}, \{\theta_v^o\}).
\]

Now for simplicity I assume all \( n_v^o \neq 0 \). You would take all \( n_v^o = 1 \), so this is, at the moment, not an important restriction.
Set
\[ M(n_\nu^0) = \frac{\int_{-\infty}^{\infty} (1 + u\bar{\nu})^{-n_\nu^0-1} \text{sign } u \, du}{\int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} du \left| \frac{t + 1/t}{2} + \frac{u}{t} \right|^{-2(n_\nu^0+1)}} \]
and let
\[ (7) \Theta(\{n_\nu^0\}) = \frac{1}{2} \{ \Pi_{v \in S_\infty} 2i \text{Im } M(n_\nu^0) \} \lim_{s \to 1} \frac{\zeta_Q(s)}{\zeta_F(s)}. \]
\( \zeta_Q \) and \( \rho_F \) are the zeta-functions of \( \mathbb{Q} \) and \( F \) respectively. The constant \( \Theta(\{n_\nu^0\}) \) will occur in the formula I shall give for (1). I have done as well as I could on extracting the explicit expression (7) for it from my notes. However when computing it one must keep careful track of factors which arise from different possible normalizations of Haar measures, so (7) is to be regarded as completely unreliable.

If \( v \) is a finite place of \( F \) we let \( f_N^v \) be the characteristic function of
\[ K(N) \cap G(F_v) = \{ g \in G(F_v) | g \equiv 1 \text{(mod } mod N) \}. \]
\( f_N^v \) is a function on \( G(F_v) \). Let \( \chi \) be a character of the idèles of \( F \) which is 1 on \( F^\times \). If \( v_2 \) is a place of \( F \), let \( \chi_v \) be the restriction of \( \chi \) to \( F_v^\times \). We suppose that \( \chi^2 = 1, \chi \neq 1 \) and that \( \chi \) is the sign character for each \( v \in S_\infty \). If \( v \) is a finite place
\[ \int_{F_v^\times} f_N^v \left( \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix} \right) \chi_v(u) |u|^s \text{d}^\times u \]
converges for \( Re \, s > 0 \). If \( v \) divides \( p \) and \( (p,N) = 1 \) this integral is 0 if \( \chi_v \) is ramified but if \( \chi_v \) is unramified it equals
\[ \frac{1}{1 - \chi_v(\sigma_v) |\sigma_v|^s} = L(s, \chi_v). \]
Set
\[ \chi(\chi, N) = \lim_{s \to 1} \Pi_{v \text{ finite}} \int_{F_v^\times} f_N^v \left( \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix} \right) \chi_v(u) |u|^s \text{d}^\times u. \]
Then $\lambda(\chi, N)$ is 0 except for a finite number of $\chi$, those which are unramified outside the places dividing $N$, and for such $\chi$

$$\lambda(\chi, N) = L(1, \chi) \prod_{v|N} \left\{ \frac{\int_{F_v^\times} f_v^N \left( \begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix} \right) \chi_v(u)|u|d^x u}{L(1, \chi_v)} \right\}.$$ 

The product on the right is elementary.

Each $\chi$ determines, by class field theory, a totally imaginary quadratic extension $E$ of $F$. Choose $t_0$, $\lambda_1$, and $\lambda_2$ as before. Let the matrix of $t_0$ with respect to $\lambda_1, \lambda_2$ be

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$ 

Then $\chi_v(b) = 1$ for almost all $v$. Set

$$\nu(E/F) = \prod_{v \text{ finite}} \chi_v(b) = \prod_{v \in S_\infty} \text{sign } b.$$ 

The alternating sum (1) is equal to

$$\Theta(\{n_v^o\}) \sum_\chi \nu(E/F) \lambda(\chi, N)$$

The sum is taken over the $\chi$ described above.

Yours truly,

R. Langlands
